20. ABSTRACT (Continue on reverse side if necessary and identify by block number) In analysis and simulation of Space-based Surveillance System Performance, a key variable is the scene/sensor interaction, under subcontract to CSDL, Photon Research Associates has developed a software package capable of generating and manipulating terrestrial scene data sets as a function of major surveillance system and mission parameters. This report documents the details of this simulation, called Genesis, which has now been incorporated into the Draper Integrated Simulations.		

ACKNOWLEDGMENT

This report was prepared by The Charles Stark Draper Laboratory, Inc., under Contract F30602-81-C-0183 and documents progress for the reporting period of June 1982 through November 1982 on the Simulation Extensions Project.

The Program Manager at CSDL is Dr. Keto Soosaar, and the Project Engineer is Mr. Thomas Brooks.

This report is based upon work performed by Photon Research Associates (PRA) under subcontract to CSDL. The Program Manager at PRA was Mr. David Anding.

Publication of this report does not constitute approval by the Defense Advanced Research Projects Agency or the United States Government of the findings or conclusions contained herein. It is published for the exchange and stimulation of ideas.

1.0 INTRODUCTION

In support of the Draper Integrated Simulations, Photon Research Associates has developed a computer code capable of generating and manipulating terrestrial scenes as a function of major surveillance system and mission parameters. This code (called GENESSIS) has the capability to interface with the Defense Mapping Agency (DMA) data base of terrestrial scenes as the source of scene input data. Consequently, the code is able to simulate any scene for which DMA data exists.

Because of the desirability to have a functioning code as soon as possible, the code is being developed in two phases (each phase spanning approximately one calendar year). The first phase has provided a functional synthetic scene simulation computer code, although this first-phase code has some limitations. In particular, some of the higher-order phenomena controlling scene radiance (e.g., cloud shadowing) have been neglected, some of the phenomenological treatments utilize simplifying approximations, and the input data base is limited to five terrestrial scenes and two cloud representations. The plan is to eliminate these restrictions during subsequent phases.

This report presents the status of the GENESSIS code at the end of the first phase effort and presents instructions for its use. Code architecture, I/O functions, user operational procedures, and test case outputs are each presented and discussed.

2.0 CODE ARCHITECTURE

The GENESIS scene simulation is based upon a point-by-point algorithm, a single cycle of which consists of collecting (and in some instances, computing) inputs specific to a single point on the scene, calculating the apparent radiance of that point from the collected inputs, and finally weighting and assigning the calculated radiance to the appropriate pixel in the observer's field of view. If the density of points is large enough, the scene will be properly sampled and the radiances computed by repeated point calculations can be combined to produce an accurate pixel radiance map of the scene. The parameters of these radiance grid points are computed from the three-dimensional scene itself.

Scene data consists of discrete altitude, material type pairs specified at regular intervals on a planar rectangular grid. Continuous surfaces are produced from the discrete scene data using a bi-cubic spline fitting technique. Point data can be computed from these surfaces at any desired spatial resolution.

The computed apparent radiances consist of four terms combined additively. These are reflected solar, thermal emission, reflected sky, and path radiance. The respective calculational procedures are discussed in Section 3.4. Each major calculational operation is performed with a separate software module. The atmospheric, geometric and radiance modules have stand-alone capabilities, but are normally executed in sequence to produce a final result.

The simulations' primary output is an $N \times M$ viewer-perspective pixel apparent radiance map. Diagnostic output is also available to check proper code execution.

2.1 Modules

The GENESIS code is comprised of six (6) modules (subroutine packages) each with a single specific task. These are geometric, atmospheric, heat transfer, radiance, image and ephemeris. These are combined into three major modules each with stand-alone capabilities. Modular stand-alone capabilities allow flexibility of operation while maintaining a simplicity of structure, user interaction and memory requirements.

The geometric module performs shadowing and the viewer perspective projection of the scene. Its output is required by the radiance module.

The atmospheric module supplies atmospheric parameters required by the radiance module. It is run least often since its output covers a wide range of solar and observer geometries.

The radiance module produces a viewer perspective pixel apparent scene radiance map from information supplied by the atmospheric and geometric modules. It calls upon the heat transfer and image modules to produce,

respectively, surface temperatures and viewer image. The heat transfer module currently does not have a stand-alone capability. Both the geometric and radiance modules utilize the ephemeris module.

With the exception of the ephemeris module, these packages are discussed in detail in Sections 3.1-3.5. The ephemeris module computes the altitude-azimuth position of the sun for any specific time, date and observer location. A published user's manual exists for this package.* See Appendix 1 for excerpts of this manual.

2.2 Module Interaction

A flow diagram of the GENESSIS architecture is given in Figure 1 which details module interaction and hierarchy. Although the ephemeris, heat transfer and image modules have stand-alone capabilities, they currently require interaction with other major modules. Plans exist to investigate increases in efficiency and flexibility potentially available by separating these modules. This will be done during Phase II of the contract. Figure 2 details the I/O-module interaction. In this figure GENESSIS is shown as having three major components.

2.3 User Inputs/Control

User inputs are categorized according to purpose. These are geometric, sensor and atmospheric. The elements of these are:

A. Geometric Inputs

1. The date and time of the simulation, used to compute the position of the sun,
2. The latitude and longitude of the viewer subsatellite point,
3. The observer altitude in kilometers.

B. Sensor Inputs

1. The vertical and horizontal angular field of view,
2. Focal plane rotation in degrees,
3. The vertical and horizontal spatial resolution in meters.

C. Atmospheric Inputs

1. Atmospheric model (six LOWTRAN standard atmospheres),
2. Aerosol model,
3. Haze model,
4. Visibility in kilometers.

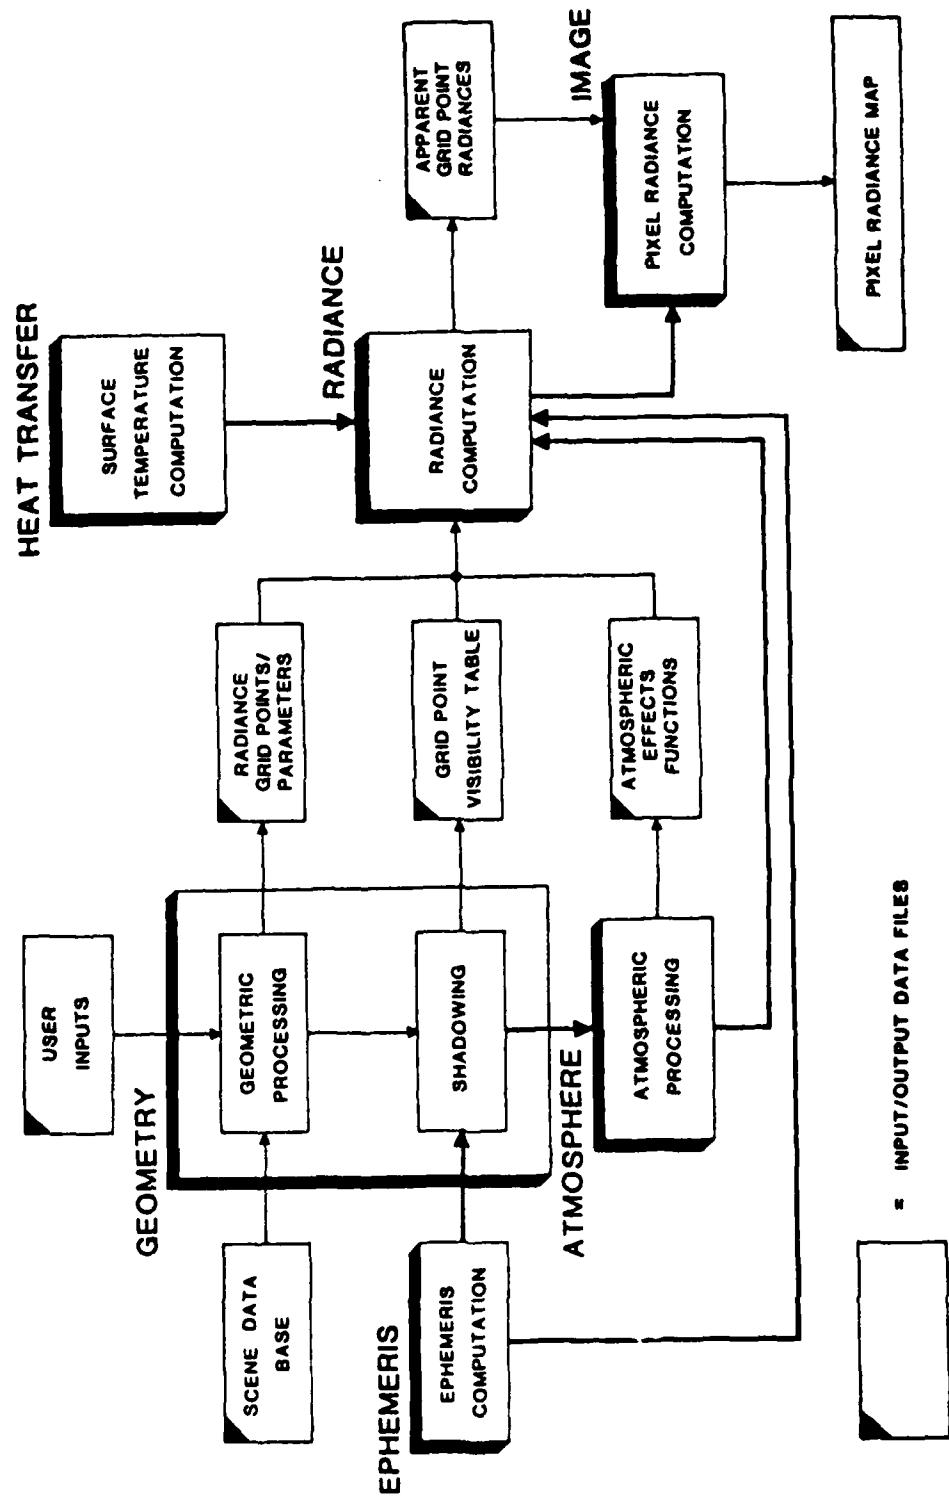

Figure 1. GENESSIS Architecture

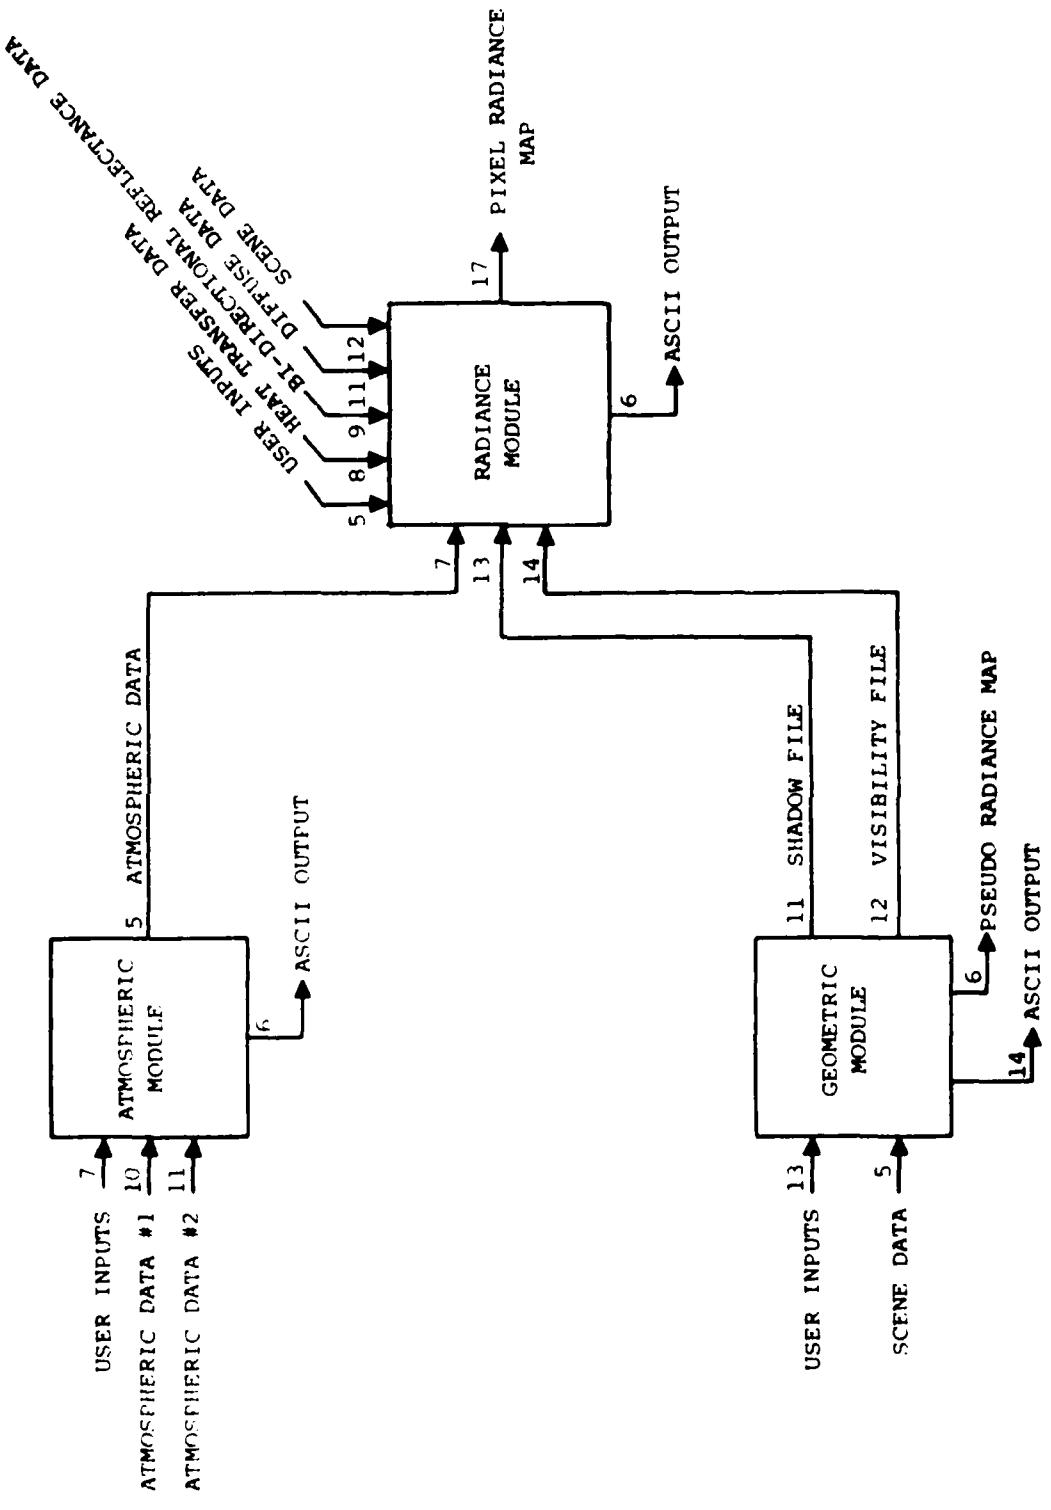

Figure 2. Overall Input/Output File Interaction. Numbers are Fortran Unit Numbers. See Section 6 for More Detail

See Section 6 for a detailed discussion of the user specified inputs.

2.4 Scene Data Base Inputs

Scene data inputs consist of the altitude, material type pairs plus thermal, atmospheric and reflectance data. The elements of these inputs are:

1. Material thermal properties (solar absorptance, thermal emittance, thermal conductance and thermal mass) required by the heat transfer module,
2. Material in-band diffuse reflectance,
3. Cloud in-band bi-directional reflectance,
4. Surface level atmospheric properties (temperature, wind speed and humidity).

A detailed discussion of the scene data base is given in Section 4.

3.0 MODULE DESCRIPTION

3.1 Atmospheric Module

The atmospheric module performs a parametric analysis of a selected standard atmosphere which is primarily a function of spectral bandpass and observer altitude. Four in-band parameters are computed. These are reflected solar, reflected skyshine, path radiance and path transmission.

The reflected components are apparent values, having been attenuated spectrally along the observer's line-of-sight path. Path transmission and path radiance are computed for the path from the surface to the observer. For the reflected components, the atmospheric module calculates spectrally for the path from source to surface to observer. The spectral data are then integrated over wavelength to produce a single in-band value for the entire path.

In order to reduce the long-term costs associated with the computation of atmospheric parameters, and to provide the necessary computational flexibility, it is desirable to have the atmospheric parameters functionally related to altitude. Early investigations showed that these parameters could be represented by polynomials over the altitude range from 0 to 10 km.

Parameters are calculated parametrically for a series of zenith angles and altitudes. At each altitude a polynomial fit versus air mass is computed and stored for reflected solar, path transmission and path radiance. For skyshine, polynomial fits are stored as a function of altitude only. From this data base, polynomial fits versus altitude for each of the four atmospheric parameters are produced for any given solar and observer position.

Since the reflected solar component is also a function of the solar zenith angle, an additional series of cases and curve fits are required to completely describe this parameter.

The coefficients of these curve fits are written to file for use by the radiance module. This output file covers all observer and solar zenith angles and need not be remade unless the bandpass, model atmosphere, observer altitude or atmospheric conditions are changed. Curve fit diagnostics are generated in order to monitor the quality of the polynomial fits.

The atmospheric module utilizes a PRA developed code which is based on LOWTRAN that properly computes reflective or "bent path" atmospheric values.

Figure 3 is a flow diagram of the atmospheric module. Figures 4-7 illustrate sample atmospheric module outputs for the following conditions:

Atmosphere::	Subarctic Summer
Observer Altitude:	100 km

3.2 Geometry

The geometric module supplies information regarding the visibility, orientation and projection of scene radiance grid points. It creates a high resolution altitude map by bi-cubic spline interpolation on a DMA data base. For each interpolated point it provides the following information:

- Point in shadow or in sun,
- Point visible or not,
- Geometric information such as altitude, normal vector, direction cosines to the sun and to the observer,
- Material type.

All geometric calculations are based on an earth-centered Cartesian coordinate system.

Surfaces and normal vectors are produced from the scene data using the bi-cubic spline fitting technique. In the event grid points are required at a higher resolution than the scene input data, they are generated from the spline-fit produced surfaces. The interpolation forms a bi-cubic patch for each grid rectangle in the data base. This rectangle is evenly divided into a sub-grid of predetermined size. The bi-cubic spline is evaluated at each of these sub-grid points. For more detailed information, see: A. R. Forrest, "On Coons' and Other Methods for the Representation of Curved Surfaces," Computer Graphics and Image Processing (1972) 1 (pp 341-359).

The visibility and shadowing of each grid point is determined using a hidden line masking technique. This is done by slicing the high-resolution data base along grid-lines, so that these slices are approximately perpendicular to the line of sight. A point is visible if the line of sight from the sensor to the point does not intersect an intervening surface. The same criterion is used for the shadowing determination. The scene is processed twice, once for the observer and once for the sun.

Shadowing and visibility information are stored in intermediate files. During the radiance calculation, these files are used to decide if the interpolated points are visible and whether they receive solar illumination. Points not visible to the observer are ignored. Points not seen by the sun are in shadow and are treated accordingly by the radiance module. The hidden line masking technique is illustrated in Figures 8-10. Projection of each point into the observer's image plane completes the primary tasks of the geometric module. The module is diagrammed in Figure 11.

3.3 Heat Transfer

Surface temperature is determined by the energy fluxes and thermal properties of the surface. The fluxes considered in the model are those resulting from solar irradiance, sky irradiance, convection to the air, self-emitted radiation, latent heat flux due to evaporation of surface moisture,* and the distributed flux through the material to a substrate. The heat balance solution of the dynamic surface temperature employs two simplifying assumptions. These are that the lateral heat flux at the surface is zero, and that the distributed heat flux to the substrate can be calculated using n discrete layers, the lowest of which is adjacent to a diurnally constant subsurface. The result and physical model and its equivalent electrical circuit are given in Figure 12.

(a) Physical Model

(b) Equivalent Electrical Circuit

FLUX DEFINITION

i_{sun}	= solar irradiance	i_{evap}	= surface evaporation
i_{sky}	= sky irradiance	i_{stored}	= layer stored
i_{emit}	= emission	i_{conv}	= air convection
i_{cond}	=	i_{cond}	= substrate conduction

Figure 12. Surface Temperature Heat Balance Model.

* For GENESIS I heat transfer due to evaporation is neglected, i.e., $\phi_{\text{evap}} = 0$.

The heat balance equation for the physical model is

$$\phi_{\text{sun}} + \phi_{\text{sky}} + \phi_{\text{stored}} = \phi_{\text{conv}} + \phi_{\text{evap}} + \phi_{\text{emit}} + \phi_{\text{cond}} \quad (1)$$

All fluxes are in units of W/m^2 and all vary with time. Each of these fluxes is expressed as follows.

The solar irradiance flux, ϕ_{sun} , is calculated by

$$\phi_{\text{sun}} = \alpha(s) E_{\text{sun}}(h, t) \cos \zeta(t) \quad (2)$$

where

$\alpha(s)$ is the effective solar absorptance,

$\zeta(t)$ is the time dependent angle between the vector to the sun and the surface normal vector, and

$E_{\text{sun}}(h, t)$ is the time dependent total solar irradiance at the surface.

The solar irradiance at the surface is given by

$$E_{\text{sun}}(h, t) = E_{\text{sun}, \Psi_0}(h) \cdot f(\Psi(t)) \quad (3)$$

where $E_{\text{sun}, \Psi_0}(h)$ is the zenith total solar irradiance as a function of surface altitude, h , and $f(\Psi(t))$ is a factor to correct for increasing atmospheric attenuation with increasing time variant solar zenith angle $\Psi(t)$.

The sky irradiance flux, ϕ_{sky} , is computed from the Idso-Jackson formula

$$\phi_{\text{sky}} = \alpha(L) \sigma T_a^4 \left\{ 1 - .26 \exp \left[-7.77 \times 10^4 (273 - T_a)^2 \right] \right\} \quad (4)$$

where

σ is the Stephan-Boltzmann constant, $5.6687 \times 10^{-8} \text{ W/m}^2 \cdot {}^\circ\text{K}$,

T_a is the ambient air temperature, and

$\alpha(L)$ is the effective thermal absorptance.

The convective flux to the atmosphere is computed by

$$\phi_{\text{conv}} = \rho c D W (T - T_a) \quad (5)$$

where

ρ is the ambient air density,

c is the specific heat of dry air,

D is the drag coefficient, empirically determined from ground truth data ranging from 0.002 to 0.01 depending upon the material,

W is the wind speed factor, equal to $1+v_w$ where v_w is the wind speed in m/sec, and

T is the surface temperature.

The latent heat flux is computed by

$$\phi_{\text{evap}} = 0.622\rho D W e(v - v_a) / p_a \quad (6)$$

where

e is the latent heat of evaporation,

v is the water vapor pressure at the surface,

v_a is the water vapor pressure of the air, and

p_a is the atmospheric pressure.

If v_a is larger than v, ϕ_{evap} is set equal to zero.

The emitted flux is computed by

$$\phi_{\text{emit}} = \epsilon(L) \sigma T^4 \quad (7)$$

where $\epsilon(L)$ is the effective thermal emittance, set equal to $\alpha(L)$ in Equation (4).

The conductance flux to the substrate is computed by

$$\phi_{\text{cond}} = g (T - T_s)$$

where g is the conductance to the substrate, equal to $\frac{l_s}{l_o} K$ where l_s is the depth at which the soil is diurnally constant and K is the soil conductivity, and T_s is the substrate temperature.

The stored flux in the surface layer is computed by

$$\phi_{\text{stored}} = \frac{l_o}{l_o} C [T(t + \Delta t) - T(t)] / \Delta t \quad (8)$$

where

l_o is the layer thickness,

C is the heat capacity of the surface material, and

ΔT is the time increment.

The solution for the surface temperature T is achieved using an interactive method wherein the surface temperature is initially chosen as the ambient air temperature at midnight, and the heat balance equation is iteratively evaluated in time increments Δt (usually set equal to 30 minutes). This iteration is continued until successive diurnal cycles match, commonly occurring within three days.

This procedure is used to produce a data base for selected materials within the scene. The data base consists of temperature and four independent variables. All independent variables are varied over a sufficient range so as to bracket all conditions that may be encountered in the scene. These independent variables are:

1. Peak solar irradiance,
2. Air-surface convective flux,
3. Substrate-surface conductive flux, and
4. Time.

The data base is compressed using a technique by which only the j most informative time points are retained of the i that were calculated. This results in a significant reduction in size of the data base (i usually 48, j/i usually 1/6) with little reduction in accuracy. The stored data base consists of four values of solar irradiances, four values of convective flux, three values of conductive flux and eight values of solar elevation angle (radians).

The heat transfer module contains data for 9 materials of the 14 total materials within GENESIS I (see Appendix 2). The 14 materials are:

<u>GENESIS Material Numbers</u>	<u>Material</u>
1*	Water
2*	Forest (Broadleaf)
3	Irrigated Low Vegetation
4	Scrub
5	Urban Commercial
6	Sand
7*	Ice
8	Rock
9	Soil
10	Grass
11*	Clouds
12	Asphalt
13	Urban Residential
14*	Forest (Pine)

* Heat transfer calculations are not performed on materials 1, 2, 7, 11 and 14.

Surface temperatures for the 5 remaining materials (i.e., 1, 2, 7, 11 and 14) are set equal to the local ambient air temperature.* Ambient air temperature varies with altitude and is computed from the user specified sea level air temperature and the atmospheric lapse rate. The lapse rate is approximately linear for each of the six standard model atmospheres between 0-10 km. The least-squares lapse rates used by GENESIS I are given in Figures 13-18.

To perform a GENESIS execution the user must specify the local air temperature and the subsoil temperature. Monthly mean temperatures are good first-order approximations to the subsoil temperature. These data are given in Tables 1-4 for each of the five generic scenes provided with GENESIS I.

3.4 Radiance Module

The radiance module computes observer apparent pixel radiances from the viewer-perspective shadow files created by the geometric module. If it is visible, an apparent radiance is computed for each of the grid points generated by the geometric modules' bi-cubic spline fit to the scene data. Pixel radiances are computed from these individually calculated grid point radiances. The apparent radiance of a specific grid point is composed of four terms combined additively. These include reflected solar, thermal emission, reflected skyshine and path radiance.

3.4.1 Reflected Solar

The apparent reflected solar component is

$$N_{\text{solar}} = \rho \Phi(h) \cos \theta_{\text{solar}}$$

where

ρ = surface in-band diffuse reflectance (bi-directional reflectance for clouds),

$\Phi(h)$ = computed fit to apparent reflected solar versus altitude (supplied by atmospheric module),

h = surface altitude in km, and

θ = local sun zenith angle (the angle between the vector to the sun and the surface normal).

* For ice, the temperature cannot exceed 0°C.

3.4.2 Thermal Emission

The thermal emission component is given by

$$N_{\text{thermal}} = \epsilon \tau(h) \int_{\lambda_1}^{\lambda_2} N(\lambda, T_s) d\lambda$$

where

ϵ = surface emissivity,

ρ = surface in-band diffuse reflectance ($1-\epsilon$),

$\tau(h)$ = computed fit to path transmission versus altitude (supplied by the atmospheric module),

h = surface altitude in km,

λ_1, λ_2 = beginning and ending band wavelengths in μm ,

$N(\lambda, T_s)$ = Planck function, and

T_s = equilibrium surface temperature in Kelvins (supplied by the heat transfer module).

3.4.3 Reflected Skyshine

The apparent reflected skyshine component is given by

$$N_{\text{sky}} = \rho \phi_{\text{sky}}(h)$$

where

ρ = surface in-band diffuse reflectance,

$\phi_{\text{sky}}(h)$ = computed fit to apparent reflected skyshine versus altitude (supplied by the atmospheric module), and

h = surface altitude in km.

3.4.4 Path Radiance

Path radiance is given by

$$N_{\text{path}} = \phi_{\text{path}}(h)$$

where

$\Phi(h)$ = computed fit to path radiance versus altitude (supplied by the path atmospheric module), and
 h = surface altitude in km.

The total apparent surface radiance returned by the radiance module for a single grid point is

$$N(i) = N_{\text{sol}}(i) + N_{\text{sky}}(i) + N_{\text{emis}}(i) + N_{\text{path}}(i)$$

where

N = total apparent grid point radiance ($\text{w/cm}^2/\text{sr}$),
 N_{sol} = apparent reflected solar radiance ($\text{w/cm}^2/\text{sr}$),
 N_{sky} = apparent reflected skyshine radiance ($\text{w/cm}^2/\text{sr}$),
 N_{emis} = apparent thermal radiance ($\text{w/cm}^2/\text{sr}$), and
 N_{path} = observer's path radiance ($\text{w/cm}^2/\text{sr}$) per the i^{th} grid point.

Two additional calculations are made by the radiance module. These are the total (over all wavelengths) solar and skyshine irradiances required by the heat transfer module.

The total surface solar irradiance was approximated utilizing LOWTRAN 5 path transmissions computed spectrally at 20 cm^{-1} resolution in the 0.25 to $4.0 \mu\text{m}$ region (nearly 99% of the sun's total exoatmospheric irradiance is emitted between 0.25 and $4.0 \mu\text{m}$) and a blackbody the size, distance and effective temperature of the sun. Exoatmospheric irradiance is attenuated spectrally and integrated over wavelength to yield the total surface solar irradiance.

Total diffuse sky irradiance is computed from a pressure compensated Idso-Jackson formulation.

Functional relations between solar and diffuse sky irradiance and altitude are computed off-line and are stored as data for each of the six standard atmospheres. The radiance module is diagrammed in Figure 19. Figures 20, 21 illustrate the functional relation between solar and diffuse sky irradiances and altitude.

Diffuse reflectance data for 11 of the 14 materials are given in Table 5. For any user-specified spectral band an average value is calculated by GENESIS. Reflectance data for urban (commercial and residential) are composites of asphalt, irrigated low vegetation and forest. Reflectance data for clouds are bidirectional data and are given in Appendix 2.

3.5 Imaging

A mean pixel radiance is computed for each pixel in the observer's image plane from the weighted sum of grid point apparent radiances projected into that pixel. That is,

$$\bar{N}_j = \frac{\sum_{i=1}^n w_i N_i}{\sum_{i=1}^n w_i}$$

where

\bar{N}_j = mean apparent radiance of pixel j ,

n = number of radiance points projected into pixel j ,

w_i = weighting factor (equal $\cos \theta_i$),

θ_i = angle between surface normal and vector to sun, and

N_i = apparent radiance of grid point, and

i = denotes the individual grid points seen by the j^{th} pixel.

The geometric module supplies both surface normal and projected grid point position in the observer's image plane. This produces an $N \times M$ viewer-perspective pixel apparent radiance map. The image module is diagrammed in Figure 22.

3.6 Code Structure Diagrams

Structure diagrams for the geometric, atmospheric and radiance modules are given in Figures 23-25. These diagrams depict the relationship between code subroutines and their hierarchy.

4.0 SCENE DATA BASES

4.1 Overview

There are five terrain data bases. Each was extracted from Defense Mapping Agency (DMA) data. The five scenes are: the California coast, the Brooks Range Mountains of Alaska, arctic tundra, Middle East, and Central Europe. All scenes were registered with Landsat data to produce complete representation of the ground cover for each point.

In addition to the five ground scenes, two cloud scenes are included. These represent a low and high altitude cloud, both with a minimum altitude of 1100 meters.

Each scene represents an area approximately forty kilometers square. DMA data is recorded at uniform angular resolution; scenes at different latitudes therefore have different spatial resolution.

4.2 File Structure

Each scene is composed of two parts: the header and the data.

Header. The header is 1024 16-bit words long. It contains the following information about the scene: the number of columns and number of rows of data, the scene center (in longitude and latitude), the scene center in X,Y,Z coordinates, the altitude scaling factors, and the spacing in kilometers between the data points in the X and Y direction. All floating-point information has been converted to an integer representation and is reconstructed by the software.

Data. The data points directly follow the header. There are (# columns) times (# rows) data points in each scene. Each data point is a 16-bit integer (binary) value and has two parts: the lower twelve bits represent the altitude of that point and the upper (left) four bits represent the material type assigned to that point. The scene is written in a row-wise format. The first row is the northernmost row.

5.0 SOFTWARE LIMITATIONS, MODEL CONSTRAINTS AND PRECAUTIONS

The following is a list of limitations, constraints, and precautions which the GENESIS user may find useful.

1. Input scene data set is currently limited to approximately 512 x 512 grid points because of computer size restrictions.
2. Output 2-D radiance map is limited to 512 x 512 pixels.
3. Data base currently limited to 14 material types.
4. Scene and/or cloud altitudes limited to 0-10 km.
5. Observer/solar zenith angles limited to 0-86 degrees due to LOWTRAN anomalies at large zenith angles.
6. Model atmospheres limited to the six standard AFGL models.
7. The atmospheric, geometric and radiance modules have some inputs in common. These must be self consistent for any single run.
8. Cloud scene shadowing is currently not handled. Cloud/scene radiance maps must be overlaid to produce a scene which contains clouds. Cloud image pixels which do not contain cloud are assigned zero radiance to facilitate this.
9. Calculations are limited to 2.5-13.0 μm .
10. Scene data bases currently limited to the five generic ground scenes and two generic cloud scenes supplied.
11. The image module currently weights path radiance which should be an unweighted component of the apparent radiance. The error introduced is small. This will be corrected in Phase II.
12. Surface level atmospheric parameters are applied uniformly over the scene. They are not spatially variable.

6.0 USER SPECIFIED INPUTS

6.1 Atmospheric Module

Card 1) IATM, ALT, WLB, WLE (I3, F10.3)

IATM - Standard LOWTRAN Model Atmosphere.

- 1 - Tropical
- 2 - Midlatitude Summer
- 3 - Midlatitude Winter
- 4 - Subarctic Summer
- 5 - Subarctic Winter
- 6 - U. S. Standard 76

ALT - Observer altitude in km.

WLB, WLE - Beginning and ending bandpass wavelengths in microns.

Card 2) IAERO1, IAERO2, IHAZE, IUPPER, M1, M2, M3, VIS (7I3, F10.3)

IAERO1 - Selects the boundary layer (0-2 km) aerosol model.

- 0, 1 - Rural
- 2 - Urban
- 3 - Maritime
- 4 - Tropospheric
- 5 - Advection Fog (default vis <0.20)
- 6 - Radiation Fog (default 0.20 < vis < 1.00)

Note: If $1 < \text{vis} < 2$, the light fog option is used with IAERO1.

IAERO2 - Selects the stratospheric (~10-35 km) aerosol model.

- 0, 1 - Background
- 2 - Aged Volcanic
- 3 - Fresh Volcanic
- 4 - Meteoric Dust

IHAZE - Selects the upper atmospheric (2-100 km) haze model.

- 0, 1 - Background
- 2 - Moderate Volcanic
- 3 - High Volcanic
- 4 - Extreme Volcanic

IUPPER - Allows modification of haze model in upper atmosphere (>35 km).

0, 1 - Normal (model selected by IHAZE unchanged)

2 - Extreme Upper (selects extreme upper atmospheric haze model)

M1, M2, M3 - The parameters M1, M2 and M3 can each take integer values between 0 and 6 and are used to modify or supplement the altitude profiles of temperature and pressure, water vapor, and ozone respectively, for any given atmospheric model specified by IATM.

M1 = 1 selects the TROPICAL temperature and pressure altitude profiles.

= 2 selects the MIDLATITUDE SUMMER temperature and pressure altitude profiles.

= 6 selects the 1962 U.S. STANDARD temperature and pressure altitude profiles.

M2 = 1 selects the TROPICAL water vapor altitude profile.

= 2 selects the MIDLATITUDE SUMMER water vapor altitude profile.

= 6 selects the 1962 U.S. STANDARD water vapor altitude profile.

M3 = 1 selects the TROPICAL ozone altitude profile.

= 2 selects the MIDLATITUDE SUMMER ozone altitude profile.

= 6 selects the 1962 U.S. STANDARD ozone altitude profile.

For most applications, M1=M2=M3=0; the profiles selected by IATM are unaltered.

VIS - Meteorological range km. Override for the boundary layer haze model.

See Figure 26 for details of the aerosol models used.

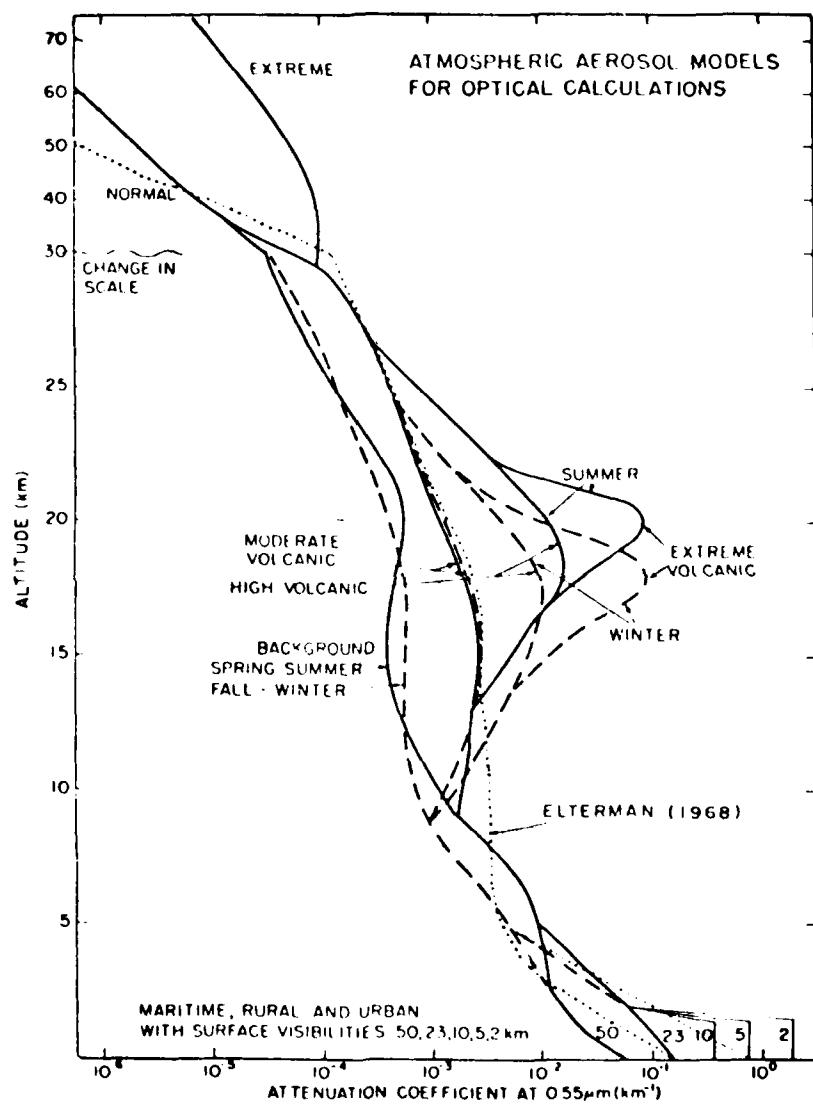

Figure 26. Atmospheric Aerosol Models Used By the Atmospheric Module

FILE UNITS

Fortran Unit	Read, Write or Read/Write	ASCII or Binary	File
5	W	A	Output data base. Contains coefficients of polynomial curve fits to atmospheric values.
6	W	A	ASCII output file. Run time diagnostics of curve fitting process.
7	R	A	User specified input file.
10	R	B	Atmospheric data base File 1.
11	R	B	Atmospheric data base File 2. This is a temporary work file.

6.2 Geometric Module

Card 1) (ISW(I), I=1, 40) (40I2)

ISW - Array of switches for debugging purposes.
(Ø - Off, 1 - On)

Card 2) DBG (A1) - Debug switch (ASCII 'T' or 'F').

Card 3) CLDMIN (F7.3) - Minimum altitude of clouds in cloud file (km).

Card 4) (SCXUSR(I), I=1,3) (3E14.6) - User Specified Scene Center.

SCXUSR(1) - Altitude (km).
SCXUSR(2) - Longitude: (DEG) - West, + East
SCXUSR(3) - Latitude: (DEG) + North, - South

Card 5) IDAY, IMONTH, IYEAR, TIME (3I5, F8.2)

IDAY, IMONTH, IYEAR - The day, month and year of the calculation. Enter as MM, DD, YYYY.

TIME - Time of run, GMT, (HHMM.SS).

Card 6) (OBSRLL(I), I=1,3) (3E14.6) - Observer position.

OBSRLL(1) - Altitude (km)
OBSRLL(2) - Longitude: (DEG) - West, + East
OBSRLL(3) - Latitude: (DEG) - South, + North

Card 7) NCOLS, NROWS (2I4)

NCOLS - Number of columns in satellite image.
NROWS - Number of rows in satellite image.

Card 8) XRESA, YRESA (2E14.6)

XRESA - Angular size of one pixel in the satellite image, in the horizontal direction (radians).
YRESA - Angular size of one pixel in the satellite image, in the vertical direction (radians).

FILE UNITS

Fortran Unit	Read, Write or Read/Write	ASCII or Binary	File
5	R	B	Scene data base.
6	W	B	Pseudo radiance used to display visible image produced.
11	W	B	Shadow file.
12	W	B	Visibility file.
13	R	A	User specified input list.
14	W	A	ASCII echo of inputs list.

6.3 Radiance Module

Card 1) IATM, IMONTH, IDAY, IYEAR, TIME (4I5, F10.2)

IATM - Standard LOWTRAN Model Atmosphere.
1 - Tropical
2 - Midlatitude Summer
3 - Midlatitude Winter
4 - Subarctic Summer

5 - Subarctic Winter
6 - U.S. Standard 76

The atmosphere selected must be the same as that in the atmospheric data base file selected.

IMONTH, IDAY, IYEAR - The month, day and year of the calculation. Enter as MM, DD, YYYY.
TIME - Time in hours (GMT) of calculation (24 hour clock, HHMM.SS).

Card 2) WLB, WLE, ALT, LONG, LAT (5F10.2)

WLB, WLE - Beginning and ending bandpass wavelengths in microns. These inputs must be the same as those in the atmospheric data base file selected.
ALT - Observer altitude in km.
LONG, LAT - Longitude and latitude of observer's NADIR point (sub-satellite point) in degrees.
 Longitude: - West, + East
 Latitude: - South, + North

Card 3) SCNALT, SCNLNG, SCNLAT (5F10.2)

SCNALT - Scene stare point (scene center) altitude in km.
SCNLNG, SCNLAT - Scene stare point (scene center) longitude and latitude in degrees.
 Longitude: - West, + East
 Latitude: - South, + North
These values override the default values read from the scene header.

Card 4) NCOL, NROW (2I5)

NCOL, NROW - Number of columns and rows in observer's apparent radiance pixel map. These are used to determine the scene F.O.V. extent (see Card 6 below).

Card 5) TAIR, TSSL (5F10.2)

- TAIR - Sea level air temperature in degrees K.
This is a 24 hr. diurnal average air
temperature.
- TSSL - Temperature of the sub-soil layer. The
temperature of that layer of sub-soil
which does not vary with the diurnal
cycle of air temperature. In general,
the mean monthly air temperature is a
good first approximation to the sub-soil
temperature (see pgs. 24-25).

Card 6) XRES, YRES (5F10.2)

- XRES, YRES - The angular extent of one pixel in the
observer's field of view in radians in
the X (vertical) and Y (horizontal)
directions. The total field of view is
then NCOL * XRES by NROW * YRES.

FILE UNITS

Fortran Unit	Read, Write or Read/Write	ASCII or Binary	File
5	R	A	User input file.
6	W	A	ASCII output file. Run time diagnostics and statistics are written here.
7	R	A	Atmospheric data base file generated by the atmospheric module.
8	R	A	Heat transfer data base.
9	R	A	Monte Carlo cloud bi-directional reflectance data.
11	R	A	Spectral material diffuse reflectance data.
12	R	B	Scene data base.
13	R	B	Shadow file generated by geometric module.
14	R	B	Visibility file generated by geometric module.
17	W	B	Pixel apparent radiance file.

APPENDIX 1

Solar Ephemeris Module User Manual

APPENDIX 1

A detailed description of the algorithm is given here, extracted verbatim* from W. Wilson, "Solar Ephemeris Algorith," University of California Visibility Laboratory, La Jolla, CA, July 1980.

This section describes the algorithm itself in terms of its logical flow and various equations and tables used.

All values computed are in degrees and fractions of degrees. For printing purposes, many times values are first converted to the form $xx^{\circ} xx' xx''$ or $xx^{\circ} xx'' xx'$. The function routine which does this is called TOHMS.

3.1. STEPS

STEP 1 Compute $p23 = T$, fraction of century from 1900 JAN 0^d 12^h ET

This routine first computes the number of days since 1900 JAN 0^d 12^h ET. The algorithm used yields a value of 694038.5 for this date. Thus, this value is subtracted to yield the actual number of days. Because the algorithm does not take proper account of the leap year century years (*i.e.* 1800, 1900) additional days need to be added for these and preceding years. To the number of whole days the standard local time (in days) and the observer's longitude is added to get the correct time; $p22 = d$ since 1900 JAN 0^d 12^h ET. This is then divided by 36525, the number of days in a century, to obtain the fraction of century, $p23$. Thus,

$$p23 = T = \frac{p22}{36525} \quad (28)$$

* Used with permission.

STEP 2(a) Compute the mean longitude of sun referenced to mean equinox of date - $p24 = L$

$$p24 = L = 279^\circ.69668 + 0^\circ.98564\ 73354 \cdot p22 + 3^\circ.03 \cdot 10^{-4} \cdot p23^2 \quad (29)$$

Note that all values are converted to the range of $0-360^\circ$ by using the function $\text{mod}(x,360)$, which is defined as the remainder of the division $\frac{x}{360}$.

STEP 2(b) Mean anomaly of sun - $p25 = M$.

$$\begin{aligned} p25 = M = 358^\circ.47583 + 0^\circ.98560\ 02670 \cdot p22 - 0^\circ.00015 \cdot p23^2 \\ - 3^\circ \cdot 10^{-6} \cdot p23^3. \end{aligned} \quad (30)$$

STEP 2(c) Eccentricity - $p26 = e$

$$p26 = e = 0.01675104 - 4.18 \cdot 10^{-5} \cdot p23 - 1.26 \cdot 10^{-7} \cdot p23^2 \quad (31)$$

STEP 3 Compute eccentric anomaly - $p13 = E$ from

$$M = E - e \cdot \sin E, \quad (32)$$

or

$$p25 = p13 - p26 \cdot \sin(p13).$$

This transcendental equation is solved for $p13$ by successive approximation. When the change in $p13$ is smaller than 10^{-8} , iteration is stopped.

STEP 4 Compute true anomaly - $p27 = V$ from

$$V = 2 \cdot \tan^{-1} \left[\frac{\sqrt{1+e}}{\sqrt{1-e}} \tan \left(\frac{E}{2} \right) \right]. \quad (33)$$

if

$$\text{sign}(V) \neq \text{sign}(E); \text{ Then } V = V + 180^\circ. \quad (34)$$

if

$$V < 0, \text{ Then } V = V + 360^\circ. \quad (35)$$

or

$$p27 = 2 \cdot \tan^{-1} \left[\frac{\sqrt{1+p26}}{\sqrt{1-p26}} \tan\left(\frac{p13}{2}\right) \right],$$

or if

$$\text{sign}(p27) \neq \text{sign}(p13), \text{ Then } p27 = p27 + 180^\circ.$$

or if

$$p27 < 0, \text{ Then } p27 = p27 + 360^\circ.$$

STEP 5(a) Compute radius vector - R

$$R = 1.0 - e \cdot \cos(E), \quad (36)$$

or

$$R = 1.0 - p26 \cdot \cos(p13)$$

STEP 5(b) Compute aberration - $p29 = \Delta\lambda_4$

$$p29 = \Delta\lambda_4 = \frac{-20.47}{R} \cdot \frac{1^\circ}{3600}. \quad (37)$$

STEP 5(c) Compute mean obliquity - $p43 = \epsilon_m$

$$p43 = \epsilon_m = 23^\circ 45.2294 - 0^\circ 01.30125 \cdot p23 - 1^\circ 64 \cdot 10^{-6} \cdot p23 + 5^\circ 03 \cdot 10^{-7} \cdot p23^3. \quad (38)$$

STEP 5(d) Compute mean ascension - $p45 = \alpha_m$

$$p45 = \alpha_m = 279.6909832 + 0.98564734 \cdot p22 + 3^\circ 8708 \cdot 10^{-4} \cdot p23^2. \quad (39)$$

STEP 6 In this step all perturbations due to the moon are computed.

The variable $p8$ controls the degree of approximation of the algorithm. If $p8 < 2$, the perturbations due to the moon are included in the algorithm.

These require the initial computation of four quantities which are:

$$\begin{aligned} \text{moon's mean anomaly} - p28 &= I \\ \text{moon's mean elongation} - p30 &= D \\ \text{moon's longitude of ascending node} - p31 &= \Omega \\ \text{moon's mean longitude} - p32 &= \gamma. \end{aligned}$$

Note that $D = \gamma - L$ where L = mean longitude of sun.

$$\begin{aligned} p28 - I &= 296^\circ.104608 + 1325 \cdot 360^\circ \cdot p23 + 198^\circ.8491083 \cdot p23 \\ &\quad + 0^\circ.00919167p23^2 + 1^\circ.4388 \cdot 10^{-5} \cdot p23^3 \end{aligned} \tag{40}$$

$$\begin{aligned} p30 - D &= 350^\circ.737486 + 1236 \cdot 360^\circ \cdot p23 + 307^\circ.1142167 \cdot p23 \\ &\quad - 1^\circ.436 \cdot 10^{-3} \cdot p23^2 \end{aligned} \tag{41}$$

$$\begin{aligned} p31 - \Omega &= 259^\circ.183275 - 5 \cdot 360^\circ \cdot p23 - 134^\circ.14200 \cdot p23 \\ &\quad + 2^\circ.0778 \cdot 10^{-3} \cdot p23^2 \end{aligned} \tag{42}$$

$$\begin{aligned} p32 - \gamma &= 270^\circ.434164 + 1336 \cdot 360^\circ \cdot p23 + 370^\circ.8831417 \cdot p23 \\ &\quad - 1^\circ.1333 \cdot 10^{-3} \cdot p23^2. \end{aligned} \tag{43}$$

The perturbation of the earth's orbit due to the mass of the moon is $p33 = \Delta\lambda$,

$$\begin{aligned} \text{where } p33 &= 6''.454 \sin D \\ &\quad + 0''.013 \sin 3D \\ &\quad + 0''.177 \sin (D+I) \\ &\quad - 0''.424 \sin (D-I) \\ &\quad + 0''.039 \sin (3D-I) \\ &\quad - 0''.064 \sin (D+M) \\ &\quad + 0''.172 \sin (D-M) \end{aligned} \tag{44}$$

Note that $D = p30$, $I = p28$, $M = p25$.

The moon also causes nutation of the solar longitude, $\Delta\psi$, and obliquity of the ecliptic, $\Delta\epsilon$. As mentioned earlier, this nutation is in terms of a power series with up to 60 terms. Table 3 has a listing

Table 3.
Series Terms for Nutation

Note. T is the fraction of century coefficient defined in the text.

of the terms of this power series. The form of each term in the series is

$$S \cdot \sin(al + bM + cF + dD + e\Omega) \quad (45)$$

for nutation in longitude, and

$$S \cdot \cos(al + bM + cF + dD + e\Omega) \quad (46)$$

for obliquity, where $F = L - \Omega$.

The algorithm as presently implemented uses only 5 terms for longitude and 4 terms for obliquity. If a higher degree of accuracy is desired more terms may be added. The terms presently used are in bold face in Table 3.

The nutation in longitude is $p34 = \Delta\psi$.

The nutation in obliquity is $p35 = \Delta\epsilon$.

The moon also has a perturbation effect on the solar latitude. For the accuracy of the present algorithm, this effect is negligible. For illustrative purposes, however, the perturbation effect is computed in the event higher degrees of accuracy are required.

The moon's mean argument of latitude, $p63$, is first computed by

$$\begin{aligned} p63 = & 11^\circ 250889 + 1342 \cdot 360^\circ \cdot p23 + 82^\circ 02515 \cdot p23 \\ & + 0^\circ 003211 \cdot p23^2. \end{aligned} \quad (47)$$

Then the perturbation of latitude due to the moon is

$$\begin{aligned} \Delta\beta = & 0''.576 \sin(p63) \\ & + 0''.016 \sin(p63 + l) \\ & - 0''.047 \sin(p63 - l) \\ & + 0''.021 \sin(p63 - 2(l - \Omega)). \end{aligned} \quad (48)$$

STEP 7 In this step perturbations due to the planets are computed. The variable $p8$ again controls the degree of approximation. If $p8 < 1$, the planetary perturbations are included.

The inequalities of the long period in the mean longitude, δL , caused by the planetary masses are computed from

$$\begin{aligned} p36 - \delta L = & 0''.266 \sin(31.8^\circ + 119^\circ \cdot p23) \\ & + (1''.882 - 0''.016 \cdot p23) \sin(57^\circ 24' + 150^\circ 27' \cdot p23) \\ & + 0''.202 \sin(315^\circ 0' + 893^\circ 3' \cdot p23) \\ & + 1''.089 \cdot p23^2 \\ & + 6''.4 \sin(231^\circ 19' + 20^\circ 2' \cdot p23). \end{aligned} \quad (49)$$

The other perturbations due to the planets all require the mean anomalies of each planet which are as follows:

VENUS:

$$p37 = 212^\circ.603222 + 162 \cdot 360^\circ \cdot p23 + 197^\circ.803875 \cdot p23 + 1^\circ.286 \cdot 10^{-3} \cdot p23^2 \quad (50)$$

MARS:

$$p38 = 319^\circ.529022 + 53 \cdot 360^\circ \cdot p23 + 59^\circ.8592194 \cdot p23 + 1^\circ.8083 \cdot 10^{-4} \cdot p23^2 \quad (51)$$

JUPITER:

$$p39 = 225^\circ.3225 + 8 \cdot 360^\circ \cdot p23 + 154^\circ.583 \cdot p23 \quad (52)$$

SATURN:

$$p40 = 175^\circ.613 + 3 \cdot 360^\circ \cdot p23 + 141^\circ.794 \cdot p23 \quad (53)$$

The perturbations due to each planet may be computed by using the mean anomalies and the coefficients from Tables 4-7. The coefficients in Tables 4-7 are given in the form of j , i , S , and K . A single term has the form

$$S \cdot \cos(K - jg' - iM), \quad (54)$$

where g' is the mean anomaly of the planet and M the mean anomaly of the sun.

Only the coefficients in bold face in the tables are used in the present algorithm. These coefficients account for most of the perturbations in longitude. Further discussion of this point is made later.

The perturbation of latitude by the planets is also negligible for the present purposes. However, if needed, a type of latitude correction may be made similar to the longitude correction. Table 8 gives the required coefficients.

STEP 8(a) Computation of precession - $p42$

The precession is defined as the distance the equinox has moved from the beginning of the year. The *rate of precession*, p , is

$$p = 50''.2564 + 0''.0222 \cdot p23 . \quad (55)$$

Thus the precession is,

$$p42 = p \cdot (\text{time since beginning of year}) . \quad (56)$$

STEP 8(b) Computation of apparent (true) longitude - $p41 = \lambda$

The apparent longitude of the sun is the solar longitude measured from the mean equinox of date apparent at the earth's surface, ignoring refraction. Thus

$$\lambda = (V - M) + L + \Delta\lambda_A + \delta L + \Delta\lambda + \Delta\psi , \quad (57)$$

or

$$p41 = (p27 - p25) + p24 + p29 + p33 + p36 + p34 .$$

STEP 8(c) Computation of obliquity $p75 = \epsilon$

$$\epsilon = \epsilon_m + \Delta\epsilon . \quad (58)$$

or

$$p75 = p43 + p35 .$$

STEP 8(d) Computation of apparent right ascension - $p44 = \alpha$

From equation 5)

$$\alpha = \tan^{-1}(\tan\lambda \cdot \cos\epsilon) . \quad (59)$$

if

$$\text{sign } \alpha \neq \text{sign } \lambda ; \text{ then } \alpha = \alpha + 180^\circ , \quad (60)$$

if

$$\alpha < 0 \text{ Then } \alpha = \alpha + 360^\circ ,$$

or

$$p44 = \tan^{-1}(\tan(p41) \cdot \cos(p43)) .$$

if

$$\text{sign}(p44) \neq \text{sign}(p41) . \text{ Then } p44 = p44 + 180^\circ .$$

or if

$$p44 < 0 \text{ Then } p44 = p44 + 360^\circ$$

STEP 8(e) Computation of equation of time - $p46 = Eq. T$.

$$Eq. T = \alpha_m - \alpha . \quad (61)$$

if

$$Eq. T > 180^\circ; \text{ Then } Eq. T = Eq. T - 360^\circ. \quad (62)$$

or

$$p46 = p45 - p44 .$$

or if

$$p46 > 180^\circ; \text{ Then } p46 = p46 - 360^\circ.$$

STEP 8(f) Computation of hour angle - $p48 = h_m$

From Eq. (26)

$$p48 = p21 \cdot 360 + 15 \cdot \text{int} \left(\frac{7.5 + p20}{15} \right) \cdot \text{sign}(p2) - p20 - 180 \quad (63)$$

where $p21$ = local standard time in fractions of days

$p20$ = absolute value of longitude

$p2$ = longitude .

STEP 8(g) Computation of local apparent hour angle - $p49 = h_s$

$$h_s = Eq. T + h_m \quad (64)$$

or

$$p49 = p46 + p48 .$$

STEP 8(h) Computation of declination - $p47 = \delta$, from Eq. (1)

$$\delta_s = \sin^{-1} \left[\cos\beta \sin\lambda \sin\epsilon + \sin\beta \cos\epsilon \right] . \quad (65)$$

or

$$p47 = \sin^{-1} \left[\cos(p60)\sin(p41)\sin(p75) + \sin(p60)\cos(p75) \right].$$

STEP 8(i) Computation of zenith angle - Z from Eq. (7)

$$Z = \cos^{-1} \left[\sin\delta, \sin\phi + \cos\delta, \cos\phi \cosh_s \right], \quad (66)$$

or

$$Z = \cos^{-1} \left[\sin(p47)\sin(p19) + \cos(p47)\cos(p19)\cos(p49) \right],$$

where $p19$ = latitude of observer.

STEP 8(j) Computation of azimuth - A from Eq. (8)

$$A = \cos^{-1} \left[\frac{\sin\delta, \cos\phi - \cos\delta, \sin\phi \cosh_s}{\sin Z} \right] \quad (67)$$

if

$$\text{sign} \left[\frac{-\cos\delta, \sin h_s}{\sin Z} \right] \# \text{ sign}(A); \text{ Then } A = 360 - A, \quad (68)$$

or

$$A = \cos^{-1} \left[\frac{\sin(p47)\cos(p19) - \cos(p47)\sin(p19)\cos(p49)}{\sin Z} \right],$$

or if

$$\text{sign} \left[\frac{-\cos(p47)\sin(p49)}{\sin Z} \right] \# \text{ sign}(A); \text{ Then } A = 360 - A.$$

The longitude tabulated in the Nautical Almanac is the apparent longitude minus the sum of the aberration and the nutation of longitude. Therefore, the tabulated quantity is

$$\lambda = (\Delta\lambda_A + \Delta\psi), \quad (69)$$

or

$$p41 = (p29 + p34).$$

3.2. ALGORITHM ACCURACY

The accuracy of the solar ephemeris algorithm depends ultimately on the number of terms used for the perturbation effects. In order to give some insight into the degree of accuracy achievable, this section will explore the effect of the various component parts on the final result.

For our specific requirements, the value of major concern is the apparent zenith angle Z . This value, computed from Eq. (7), is a function of declination δ_s , observer latitude ϕ and solar hour angle h_s . Thus

$$\cos Z = \sin \delta_s \sin \phi + \cos \delta_s \cos \phi \cos h_s . \quad (70)$$

We also know

$$h_s = h_m + Eq. T = h_m + \alpha_m - \alpha , \quad (71)$$

or, combining known quantities,

$$h_s = LMT - \alpha - \Lambda + C . \quad (72)$$

Thus taking derivatives and assuming the maximum possible error for each component, one obtains

$$\Delta Z \approx \Delta \delta_s + \Delta \alpha + \Delta LMT + \Delta \Lambda + \Delta \phi . \quad (73)$$

It should be noted that the maximum possible error will not occur simultaneously for each of the components. Thus the maximum error $\Delta \Lambda$ will occur when $\phi=0$, while the maximum error $\Delta \delta_s$ will occur when $\phi=0$, $\delta_s=0$ but $h_s = 0^\circ$ or 90° . By doing the analysis in this manner however, the relative importance of each component is illustrated.

The present requirements for the algorithm have been to compute ΔZ to within $0^\circ.1$ or $6'$. If this error is then divided proportionally among the five components, each must have maximum errors of $0^\circ.02$ or $72''$.

3.2.1. Latitude and Longitude

Since $0^\circ.02$ of latitude is 1.2 nautical miles, this fixes the required latitude determination. A longitude increment of $0^\circ.02$, in terms of surface distance is given by

$$\frac{0^\circ.02}{\cos \phi} . \quad (74)$$

However, the maximum error $\Delta \Lambda$ is proportional to $\cos \phi$, so that again a determination of Λ to within 1.2 nautical miles will give the requisite accuracy.

3.2.2. Time

A change in arc degrees of $0^\circ.02$ in zenith angle is equivalent to 4.8 seconds of time. Again, this is proportional to $\cos \phi$, so that at higher latitudes this requirement is relaxed.

3.2.3. Declination

Declination is computed using Eq. (4). Thus,

$$\sin \delta_s = \sin \lambda \cdot \sin \epsilon . \quad (75)$$

and therefore

$$\Delta\delta_s = \left(\frac{\sin\lambda \cos\epsilon}{\cos\delta_s} \right) \Delta\epsilon + \left(\frac{\cos\lambda \sin\epsilon}{\cos\delta_s} \right) \Delta\lambda . \quad (76)$$

Since ϵ , the obliquity is on the order of $23^\circ.5$, the maximum error for $\Delta\epsilon + \Delta\lambda$ is on the order of

$$\Delta\delta_s = \Delta\epsilon + 0.4 \times \Delta\lambda . \quad (77)$$

For $\Delta\delta_s = 0^\circ.02$, and dividing maximum error proportionally

$$\Delta\epsilon = 36'' \quad (78)$$

and

$$\Delta\lambda = 90'' = 1' 30'' .$$

3.2.4. Right Ascension

From Eq. (5), right ascension α is computed as

$$\tan\alpha = \tan\lambda \cdot \cos\epsilon , \quad (79)$$

or

$$\Delta\alpha = \frac{\sec^2\lambda \cos\epsilon}{\sec^2\alpha} \cdot \Delta\lambda + \frac{\tan\lambda \sin\epsilon}{\sec^2\alpha} \cdot \Delta\epsilon . \quad (80)$$

Putting in values for maximum error, the relationship

$$\Delta\alpha = \Delta\lambda + 0.7 \cdot \Delta\epsilon \quad (81)$$

is obtained.

For $\Delta\alpha = 0^\circ.02$ and dividing the maximum error proportionally,

$$\Delta\epsilon = 90'' = 1' 30'' \quad (82)$$

and

$$\Delta\lambda = 36'' .$$

3.2.5. Obliquity and Solar Longitude

The analysis of errors due to declination and right ascension shows that in general for $\Delta Z = 0^\circ.1$, the error in obliquity $\Delta\epsilon$ should be less than $36''$. This is also true for the error in solar longitude $\Delta\lambda$.

The major source of error in obliquity is the inclusion of the nutation of obliquity $\Delta\epsilon$. Addition of all of the coefficients for nutation of obliquity found in Table 3 gives the sum $10''.04$. If the four highest terms are summed the value $9''.94$ is obtained.

Thus the maximum possible error in obliquity is not $36''$ but on the order of $10''$. If the four largest terms for nutation of obliquity are used this reduces the maximum error to $0''.1$. Therefore the maximum error for longitude $\Delta\lambda$ may be increased to $62''$ or $72''$.

The errors in the computation of longitude are listed in Table 9 along with the corrections used in the present algorithm. The errors are computed by adding the coefficients given in Tables 3 and 4.

Table 9.

	All Corrections	Algorithm Corrections	# of Terms
Nutation of Long $\Delta\phi$	19° 36'	19° 03'	5
Moon perturbation of long $\Delta\lambda_m$	7° 34'	7° 34'	7
Inequalities of Long Period ΔL	9° 84'	9° 84'	5
Perturbations of Planets			
VENUS	17° 57'	16° 11'	6
MARS	7° 02'	5° 60'	6
JUPITER	15° 65'	14° 71'	5
SATURN	1° 04'	0° 74'	2
TOTAL	77° 82'	73° 37'	

It can be seen from Table 9 that the maximum error $\Delta\lambda$ is about 78''. This is just 16'' higher than the maximum allowable error of 62'' from $\Delta Z = 0^\circ.1$. Since this is the maximum allowable error, the computation of λ without any nutation and perturbation corrections should allow Z to be computed to within $0^\circ.1$ under most conditions.

The addition of the nutation terms in the obliquity and longitude calculations using only those 9 terms used in the present algorithm will reduce the maximum allowable error in longitude to 49'' which is well within the requirement.

The use of all the terms for nutation and perturbations in the present algorithm reduces the error in longitude computation on the order of 4''.5. This degree of accuracy is far greater than is needed for most applications. Their inclusion has been merely an illustration of the technique required for a highly accurate solar ephemeris.

3.2.6. Sample Results

To show the accuracy of the algorithm, the ephemeris for four days have been computed and tabulated below. They are:

Table 10 1786 MAY 3, 17^h 30^m GMT

Table 11 1960 MAR 1, 0^h GMT

Table 12 1979 JAN 1, 0^h GMT

Table 13 1979 JUL 1, 0^h GMT

The first date was chosen because Newcomb used this date as an example as to how to use the "tables". The second date is used in the *Supplement* as an example, and the last two are merely illustrative of the accuracy for the year 1979.

For each date the computations have been made for the approximations noted in the sections above. The first uses the full algorithm, the second excludes planetary effects, while the third excludes lunar and planetary effects.

Table 10. 1786 MAY 4 5^h30^m GMT

	Nautical Almanac	Algorithm Full	Algorithm no planetary effects	Algorithm no lunar effects
Longitude for Mean Equinox of Date	43° 50' 49" 5	43° 50' 51" 7	43° 50' 57" 3	43° 50' 54" 6
Reduction to Apparent Longitude	-6° 02	-6° 11	-6° 11	-20° 28
Latitude for ecliptic of Date	.	-0° 01	0° 02	.
Precession in Longitude from 1786.0 to Date	17° 06	17° 22	17° 22	17° 22
Nutation in Longitude	14° 26	14° 17	14° 17	.
Nutation in Obliquity	4° 13	4° 30	4° 30	.
Obliquity of Ecliptic	23° 28' 05" 8	23° 28' 05" 8	23° 28' 05" 8	23° 28' 01" 5
Apparent Right Ascension	.	2 ^h 45 ^m 31 ^s 6	2 ^h 45 ^m 20 ^s 1	2 ^h 45 ^m 31 ^s 0
Apparent Declination	.	16° 00' 50" 0	16° 00' 51" 8	16° 00' 43" 9
Radius Vector	1.0093	1.0093	1.0093	1.0093
ET of Ephemeris Transit	.	11 ^h 50 ^m 30 ^s 3	11 ^h 50 ^m 30 ^s 6	11 ^h 56 ^m 29 ^s 6

*Note that previous to 1925 GMT was measured from Greenwich noon. Thus Newcomb computed ephemeris for 1786 May 3 17^h30^m GMT.

Table 11. 1960 MARCH 7 0^h GMT

	Nautical Almanac	Algorithm Full	Algorithm no planetary effects	Algorithm no lunar effects
Longitude for Mean Equinox of Date	346° 26' 23" 5	346° 26' 24" 3	346° 26' 04" 5	346° 26' 01" 9

APPENDIX 3

Test Cases

Two test cases are presented and described herein. They were run on a small section of the Brooks Range scene. Measured data from Daedalus exists for this scene. All GENESIS input parameters were selected to match the conditions present at the time of Daedalus data acquisition in order that the computed results may be compared with the measured data.

A.3.1. Test Case I - Brooks Range (Thermal Band)

A.3.1.1 Atmospheric Module

Display of input file (Fortran Unit 7) for Brooks Range thermal band.

1)	3	16.76	10.4	12.5			
2)	1	1	1	0	0	0	23.0

Display of atmospheric diagnostic output file (Fortran Unit 6).
Selected standard atmosphere is represented parametrically for 5 zenith
angles and 6 altitudes. Air masses are computed using the Chapman function.

RESULTS FOR BACKGROUND ALTITUDE = 0 KM

DEGREE OF BEST FIT POLYNOMIAL: 4
SUM SQUARE ERROR 9 948E-13

PATH RADIANCE

DEGREE OF BEST FIT POLYNOMIAL: 4
SUM SQUARE ERROR 2 010E-10
FIT OF SKYSHINE TO ALTITUDE
DEGREE OF BEST FIT POLYNOMIAL: 5
SUM SQUARE ERROR c 323E-10

Display of atmospheric module output database (Fortran Unit 5). Header (Line 1) contains parameters used to generate the database. Lines 2-44 contain the coefficients of the polynomial curve fits to the computed atmospheric values.

Hex display of the binary shadow map (Fortran Unit 11).

Visibility map (Fortran Unit 12). Since this test case is a nadir view, all points are visible to the observer. Therefore, the entire visibility map is composed of zeros and is not displayed.

ASCII display of a portion of the binary pseudo radiance map (Fortran Unit 6). One third of the scene (leftmost portion) is shown. Columns 1-10 are uniformly zero (the field of view extends beyond the edge of the scene) and are not included.

A.3.2 Test Case II - Brooks Range (Solar Band)

A.3.2.1 Atmospheric Module

Display of input file (Fortran Unit 7) for Brooks Range solar reflective band.

1)	3	16.76	3.6	4.0
2)	1	1 1 0 0 0	23.0	

Display of the atmospheric diagnostic output file (Fortran Unit 6). Selected standard atmosphere is represented parametrically for 5 zenith angles and 6 altitudes. Air masses computed using the Chapman function.

RESULTS FOR BACKGROUND ALTITUDE = 0 KM

Display of the atmospheric module output data base (Fortran Unit 5).
 Header (Line 1) contains parameters used to generate the database. Lines 2-44 contain the coefficients of the polynomial curve fits to the computed atmospheric values.

A.3.2.2 Geometric Module

Case II is also a nadir view and a new geometric run is not required.

A.3.2.3 Radiance Module

Display of user specified input file (Fortran Unit 5).

1)	3	9	1	1981	2210.
2)		3.6		4.0	16.76
3)		0.		-149.5	67.78

MATERIAL	MEAN	SDEV	MIN	MAX
8	2.823E 02	3.006E 00	2.779E 02	2.900E 02

APPARENT SCENE RADIANCE (W/CM**2/SR)

MATERIAL	MEAN	SDEV	MIN	MAX
8	1.515E-05	8.637E-06	1.354E-06	2.511E-05

DIFFUSE OR BI-DIRECTIONAL REFLECTANCE

MATERIAL	MEAN	SDEV	MIN	MAX
8	1.520E-01	0.000E-01	1.520E-01	1.520E-01

ASCII display of a portion of the binary radiance map output file (Fortran Unit 17). One third of the scene (leftmost portion) is shown. Columns 1-10 are uniformly zero (the field of view extends beyond the edge of the scene) and are not included.

MISSION
of
Rome Air Development Center

RADC plans and executes research, development, test and selected acquisition programs in support of Command, Control Communications and Intelligence (C³I) activities. Technical and engineering support within areas of technical competence is provided to ESD Program Offices (POs) and other ESD elements. The principal technical mission areas are communications, electromagnetic guidance and control, surveillance of ground and aerospace objects, intelligence data collection and handling, information system technology, ionospheric propagation, solid state sciences, microwave physics and electronic reliability, maintainability and compatibility.
